Abstract

There are only a few published bat surveys from the southwestern Brazilian Amazon, but recent studies have reported additional bats species in the region. We provide the first list of bat species from Floresta Estadual do Antimary (Antimary State Forest) and record for the first time *Glyphonycotis sylvestris* Thomas, 1896 and *Phylloderma stenops* Peters, 1865 in the state of Acre, increasing to 64 the number of species known from this state. Our survey enlarges the known geographic range of *G. sylvestris* in Brazilian territory and improves the inventory of bat species in a poorly sampled region of the Amazon.

Keywords

Amazonia, chiropteran diversity, distribution

Introduction

The Neotropical region harbors the greatest species richness of mammals in the world (Burgin et al. 2018). Efforts toward recognizing and recording the biodiversity of mammals have been historically heterogeneous in various Brazilian regions. Biodiversity surveys are usually focused in areas close to urban centers, which concentrate research institutions and along roads and navigable

rivers (Boakes et al. 2010; Oliveira et al. 2016). The Amazon region, given its large area and difficulty of access, represents an enormous knowledge gap in the diversity and distribution of bat species (Bernard et al. 2011).

In Brazil, the order Chiroptera is represented by nine families, 68 genera, and 181 species (Garbino et al. 2020), with records of 160 species in the Amazon biome

(López-Baucells et al. 2016). According to Bernard et al. (2011), 59 bat species occur in the state of Acre, but five species were recently recorded: *Gardnerycteris crenulatum* (É. Geoffroy, 1803), *Lasiurus blossevillii* (Lesson, 1826), *Lophostoma brasiliense* Peters, 1866, *Micronycteris microtis* Miller, 1898, and *Saccopteryx canescens* Thomas, 1901 (Calouro et al. 2010; Verde et al. 2017, 2018).

In the southwestern Amazon, bamboo species of the genus *Guadua* (Bambusoideae: Poaceae) have ecological characteristics that influence the structure and dynamics of forests (Silveira 2005). About 161,500 km² of the southeastern Amazon region is occupied by forest with a high density of bamboo (Carvalho et al. 2013) infer the life-cycle length and describe spatial and temporal patterns of flowering of sarmentose bamboos (*Guadua* spp, which, once established, changes succession and forest dynamics and functions as a biotic filter. *Guadua* species have a life cycle of about 29–32 years (Silveira 2005; Carvalho et al. 2013), with opportunistic growth and a high capacity to occupy altered areas, which give the bamboo a significant competitive advantage (Silveira 2005). These factors, plus the uncommon life cycle of synchronized mortality after fruiting, directly affect the vegetation dynamics, appearance, vegetation structure,

and composition of tree species of the forest (Silveira 2005). Open forests dominated by *Guadua* are called “tabocais” and, although uncommon in the Amazon, cover large areas in the southwestern Amazon (Silveira 2005). Floresta Estadual do Antimary (FEA; Antimary State Forest is located in the center of the distribution of *Guadua* bamboo species in the Amazon (McMichael et al. 2014), and in Acre this is most protected areas are within the distribution of *Guadua* species.

Although there are over 10 protected areas in Acre, including integral and sustainable-use protected areas, bats have only ever been surveyed in Serra do Divisor National Park (Nogueira et al. 1999). Thus, there remains gaps in the knowledge of the real diversity and distribution of these mammals in the state. Therefore, this is the first Chiroptera survey carried out in the FEA, northeastern Acre state, and expands efforts to catalog the bat fauna in one of the less sampled areas of the Amazon.

Methods

Study site. We conducted a bat survey in the FEA (Fig. 1) located in the southwestern Brazilian Amazon, in northeastern Acre. The FEA encompasses the municipalities of Bujari and Sena Madureira, bordering to the

northeast with the state of Amazonas and to the south with the Antimary River. It has an area of 76,832 ha and is comprised of a mosaic of dense forest and open forest with bamboo, including species of the genus *Guadua*, and/or palm trees (Funtac 2012). The predominant vegetation at the two sampling sites is dense rainforest is the

forest dominated by bamboo and palm trees. The annual air temperature in the region ranges from 22 to 33 °C and annual rainfall from 1,600 to 2,750 mm. The climate is Am according to the Köppen classification system (Alvarres et al. 2013), and there is an increased rainy period from November to April and drier from May to October.

Field surveys. We captured bats in a total of nine sampling nights in June 2016 and March 2017 during four and five nights, respectively. Each night we used eight Ecotone® mist nets (12 × 3 m, 19 mm mesh size) placed at ground level. The nets were left open for 6 h and inspected every 15 min. The final sampling effort was 15,552 m² · h following Straube and Bianconi (2002).

Identification and voucher specimens. We identified the bats in the field using the identification keys by Gardner (2007) and Díaz et al. (2016). The species caught were classified into five guilds according to Schnitzler and Kalko (1998) and Simmons and Voss (1998): glean-ing frugivore, glean-ing insectivore, aerial insectivore, glean-ing carnivore, and glean-ing omnivore. We kept the bats in cotton bags for morphometric for identification and aging by observing the ossification of epiphyses of the third metacarpus (Kunz and Anthony 1982; Kunz and Robson 1995). We released the bats where they were captured. We euthanized a few voucher specimens of each species by the intramuscular injection of 100 g/kg of ketamine hydrochloride combined with 1% acepromazine at the ratio of 9:1. These specimens were then identified in laboratory using external, cranial, and dental characteristics. We fixed the specimens in 10% formalin for storage in a 70% alcohol solution and deposit in the Laboratório de Ecologia dos Mamíferos (LEM) of the Universidade Federal do Acre. The captures and specimen collections were authorized by SISBIO (Sistema de autorização do Instituto Chico Mendes de Conservação da Biodiversidade) (authorization number 56970).

To confirm the identification of our specimens, we measured the external body, skull, and teeth: weight (in grams), forearm length; total length, the distance between the tip of the muzzle to the tip of the last tail vertebra; tibia length, distance from the proximal tip of the tibia to the posterior base of the calcaneus; ear length, from the notch to the tip of the auricle; tail length, distance from the dorsal tail flexure with the sacrum to the tip of the last tail vertebra; skull maximum length, from the proximal point on the occipital to the distal point over the premaxilla (excluding the incisors); zygomatic width, the largest distance between the zygomatic arches. All biometrics were measured using digital calipers with 0.01 mm precision.

Data analysis. The capture rate was calculated by dividing the number of captures by the total sampling effort (individuals/m² · h · net). Richness was estimated according to the Jackknife 1 method (Colwell and Conditon 1994) using PAST v. 3.0 (Hammer et al. 2001). We also built the species accumulation curve based on the sample randomization using the vegan package (Oksanen et al. 2011) in R v. 3.0.3 program (R Core Team 2015).

Results

Assemblage structure. We captured 99 individuals belonging to 19 species, 15 genera, and two families. The

gleaning frugivores were predominant ($N = 72$, species = 11), followed by insectivores ($N = 23$, species = 5), omnivores ($N = 3$, species = 2) and carnivores ($N = 1$, species = 1) (Table X). Total capture index was 0.006 ind · m² · h · net. The result of the Jackknife 1 richness estimator indicated that the local assemblage hosts 24 ± 1.88 species, which indicates that our sampling represented 79% of the potential richness in the locality. Likewise, the accumulation curve did not reach an asymptote, indicating that more species can be recorded with additional sampling efforts (Fig. 2).

Order Chiroptera

Family Phyllostomidae

Carollia perspicillata (Linnaeus, 1758)

Figure 3E

Materials examined. BRAZIL • 9 adult ♀, 6 adult ♂; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; alt. 200 m a.s.l.; Jun. 2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1153 (Fig. 3E).

Identification. Lower jaw tending to be V-shaped, with straight rami. Short pelage with bands with contrasting colors and a light band greater than the dark one. Forearm ranged from 38 mm to 44 mm. Cingula of canine hiding the outer mandibular incisors. Conspicuous hair on the forearm and toes; by intermediaries in the tibia.

Carollia brevicauda (Schinz, 1821)

Figure 3D

Materials examined. BRAZIL • 1 adult ♀, 2 adult ♂; Acre, municipality of Sena Madureira, Antimary State Forest; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun.

Identification. Nasal leaf with smooth edges and horse-shoe cast with upper lip; first superior premolar separated from third premolar, and second premolar not displaced from lingual face. Measurements: total length 95.2 mm; tail length 11.8 mm; hind foot length 27.7 mm; ear length 24.5 mm; forearm length 74.1 mm; tragus 9.2 mm.

***Phyllostomus elongatus* (É. Geoffroy, 1810)**

Figure 3H

Materials examined. BRAZIL • 2 adult ♂; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun.

2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1159 (Fig. 3H).

Identification. Forearm 63–65 mm long; tibia longer than 23 mm; greatest length of skull more than 29 mm; lower incisors trifid.

***Tonatia maresi* Williams, Willig & Reid, 1995**

Figure 3N

Materials examined. BRAZIL • 4 adult ♀, 6 adult ♂; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun. 2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1160 (Fig. 3N).

Identification. Skin around mouth, nose leaf, and warts

of lower lip darkly colored; posterior edge of cranium with blunt vertex due to a poorly developed sagittal process; canine and first lower premolar separated by a diastema; clinoid process poorly developed or absent.

***Trachops cirrhosus* (Spix, 1823)**

Figure 3O

Materials examined. BRAZIL • 1 adult ♂; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Mar. 2017; R.S. Verde leg.; collected with mist nets; voucher: LEM-1161 (Fig. 3O).

Identification. Papilla-like protuberances present on chin and lips; nose-leaf with finely serrated margins; tail extends to the middle of the interfemoral membrane; calcar about equal in length to foot.

***Glyphoncteris sylvestris* Thomas, 1896**

Figure 3T

Materials examined. BRAZIL • 1 adult ♂; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Mar. 2017; R.S. Verde leg.; collected with mist nets; voucher: LEM-1162 (Fig. 3T).

Identification. Dorsal hair tricolored; greatest length of skull less than 25 mm; two pairs of upper incisors, outer incisor hidden by cingulum of canine; lower incisors normal (not anteriorly-posteriorly long and transversely narrow). Morphological characteristics (external, cranial and dental) observed in the collected specimen allowed the correct identification. Measurements (in mm) obtained from the collected male: forearm length 39.9, third metacarpal 36.6, fourth metacarpal 35.3, fifth metacarpal 38.2, total skull length 19.8, basal condyle length 18.2, series of upper teeth 8, length of mandible 12.8, series of lower teeth series 8.3, zygomatic width 9.7, cranial cavity width 8.2.

Comments. Our record expands the distribution of *G. sylvestris* by nearly 650 km northwest of the nearest Amazon record (Tirira et al. 2016).

***Trinycteris nicefori* (Sanborn, 1949)**

Figure 3P

Materials examined. BRAZIL • 4 adult ♀; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun. 2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1163 (Fig. 3P).

Identification. Forearm 39.6 mm; dorsal pelage four-banded; pale basal band narrow and inconspicuous; pale median dorsal stripe usually evident on the lower back; upper incisors wide and spatulate; lower lip Y-shaped; brown dorsal hair; first upper premolar small, smaller than the second premolar.

***Artibeus cinereus* Gervais, 1856**

Figure 3F

Materials examined. BRAZIL • 1 adult ♀; Acre, muni-

cipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun. 2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1167.

Identification. Forearm 38–40 mm; dorsal hair bicolored; molars 2/2; interfemoral membrane appearing practically hairless (Fig. 3F).

***Artibeus planirostris* (Spix, 1823)**

Figure 3C

Materials examined. BRAZIL • 4 adult ♀, 4 adult ♂; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun. 2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1164 (Fig. 3C).

Identification. Forearm 63–69 mm; facial lines not evident; molars 3/3; tip of the pale wing; nasal leaf with free lower edge.

***Artibeus lituratus* (Olfers, 1818)**

Figure 3A

Materials examined. BRAZIL • 7 adult ♀, 8 adult ♂; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun. 2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1165 (Fig. 3A).

Identification. Forearm 69–74 mm; facial stripes prominent and well defined; molars 2/3; tragus and lower margin of ears pale.

***Artibeus obscurus* (Schinz, 1821)**

Figure 3B

Materials examined. BRAZIL • 1 adult ♀, 2 adult ♂; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun. 2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1166 (Fig. 3B).

Identification. Forearm 55–59 mm; fur long and blackish; tubercles on lower lip small, usually 3 or 4 on each side of chin.

***Platyrrhinus brachycephalus* (Thomas, 1912)**

Figure 3I

Materials examined. BRAZIL • 1 adult ♂; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Mar. 2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1168 (Fig. 3I).

Identification. Anterolingual cristid of fourth lower premolar with two well-developed accessory cusplids; forearm 43 mm; venter tricolor; facial stripes inconspicuous.

***Platyrrhinus incarum* (Thomas, 1912)**

Figure 3J

Materials examined. BRAZIL • 1 adult ♀; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun.

2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1169 (Fig. 3J).

Identification. Anterior border of main cusp of last premolar with 1 or 2 major cusps; ventral hair bicolor; lateral borders of proximal half of nasal leaf and horseshoe white.

***Uroderma bilobatum* Peters, 1866**

Figure 3Q

Materials examined. BRAZIL • 2 adult ♀; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun. 2016; R.S. Verde leg.; collected with mist nets; hair color, forearm size and dentition; voucher: LEM-1170 (Fig. 3Q).

Identification. ventral pelage dark; facial stripes prominent; ear margin yellowish in life; interfemoral membrane nearly naked; rostrum shallow; forearm 43–45 mm.

***Vampyressa thyone* Thomas, 1909**

Figure 3R

Materials examined. BRAZIL • 1 adult ♀; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun. 2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1266 (Fig. 3R).

Identification. Small size, forearm 32.7 mm; maximum length of skull 18.5 mm; zygomatic breadth 10.4 mm; mandibular tooththrow 6.1 mm; dorsal stripe absent.

Family Thyropteridae

***Thyroptera tricolor* Spix, 1823**

Figure 3M

Materials examined. BRAZIL • 1 adult ♀; Acre, municipality of Sena Madureira, Floresta Estadual do Antimary; 09°18'41.19"S, 068°17'34.58"W; 200 m a.s.l.; Jun. 2016; R.S. Verde leg.; collected with mist nets; voucher: LEM-1171 (Fig. 3M).

Identification. Forearm 36.8 mm; ventral pelage solid white or pale gray; interfemoral membrane appearing nearly naked; inner upper incisor bifid.

Discussion

The most common species in our study belonged to the genus *Carollia*. *A. lituratus*, *R. pumilio* and *T. maresi* were moderately abundant. The frugivorous guild was most prevalent and represented 72% of the species captured. Other studies in the Amazon also reported the abundance of individuals of the genus *Carollia* (e.g. Bernard and Fenton 2007; Presley et al. 2009; Bobrowiec and Gribel 2010; Bobrowiec 2012; Tavares et al. 2017), which is often associated plants of the genus *Piper* on which it feeds. Insectivores amounted to 22.8% of the individuals caught, and omnivores and carnivores accounted for less than 3%. The presence of species which are usually less often caught in mist nets, such as *P. stenops*, *G.*

sylvestris, and *T. nicefori*, shows that our study area is probably well-conserved.

Of the species that we newly report from Acre, *P. stenops* is widely distributed, occurring from Mexico to southeastern Brazil, and in Andes at elevations up to 2,900 m (Gardner 2007). In Brazil, there are records in the Amazon, Atlantic Forest, and Cerrado (Esbérard and Faria 2006; Bernard et al. 2011). This is an omnivorous species that feeds on fruits (Annonaceae, Cucurbitaceae, Myrtaceae, Urticaceae, among others) and insects, including social wasps (Jeanne 1970; Giannini and Kalko 2004). Despite its wide distribution, *P. stenops* is relatively poorly sampled using mist nets (Bomfim et al. 2017). Consequently, there are still many gaps in its known distribution. Esbérard and Bergallo (2005) captured this species at locations highly rich in bat species, and Bomfim et al. (2017) captured it in a relatively small fragment of Atlantic Forest with the use of nets in the canopy (Even in primary forests, only a few individuals have been captured, which suggests that this species probably has a low natural density (Clarke and Downie 2001), or it is possible that it uses the canopy and, therefore, is less likely to be captured in mist nets at ground level.

Overall, *G. sylvestris* is widely distributed in the Neotropical region, but its records are occasional and dispersed, with a low capture rate (Williams and Genoways 2008; Zortéa and Alho 2008). There are records in western Mexico, Trinidad, Panama, Colombia, Venezuela, Peru, Suriname, French Guiana, southeastern Brazil, and Argentina (Gardner 2007; Morales-Martinez and Suarez-Castro 2014; Sánchez et al. 2019), and recently in Ecuador (Tirira et al. 2016) and the Brazilian Cerrado (Felix et al. 2016). This species forages mainly for fruits and insects and inhabits humid, deciduous forests (Goodwin and Greenhall 1961; Williams and Genoways 2008). It especially occurs in primary forests but only occasionally in secondary forests and clearings (Ochoa and Velazco 2008; Tirira et al. 2016).

Where *Guadua* bamboo occurs in mature forests, the changes in the dynamics, appearance, and structure of the forest (Silveira 2005) is as they would be in secondary forests (Carvalho et al. 2013). These changes to forests caused by bamboo, as well as the life cycle of *Guadua*, which is estimated as 28 years (Carvalho et al. 2013), are important for understanding how bat assemblages persist in these environments over time. Our study is one of the first on bat diversity within a bamboo-dominated forest in the southwestern Amazon region.

In the state of Acre, the sampling of chiropterofauna is concentrated in the extreme west. The first studies were carried out by Taddei et al. (1990) and Nogueira et al. (1999), who reported 56 species, including the first records of *Sturnira magna* de la Torre, 1966 and *Pro-mops centralis* Thomas, 1915 in Brazil. An increase sampling effort in the eastern portion of Acre has also increased the number of species known from the state (Marciente and Calouro 2009; Calouro et al. 2010; Verde

et al. 2017; Santos et al. 2018; Verde et al. 2018; Pedroza et al. 2019; Silva et al. 2020). However, there still exists unexplored areas and probably some additional species w yet recorded.

Acknowledgements

We thank the the Postgraduate Program Mestrado de Ecologia e Manejo de Recursos Naturais and the Laboratório de Ecologia de Mamíferos (Universidade Federal do Acre), which contributed with all field logistics and materials for procedures to identify the animals collected. We also thank the reviewers and editors of the Check list for corrections for their comments and advice on earlier drafts of this manuscript.

Authors' Contributions

RSV and AMC designed of the study, provided materials for the fieldwork, captured the bats, and identified the bats in the laboratory. SFO, AOM, FG, LA, TMS, and EFM collected, sorted identified, and prepared voucher specimens, and wrote the first draft of the manuscript. RSV, AMC, and HAM did the analysis and wrote the final draft of the manuscript.
